# Structure-Aware Adapter for Large Language Model

## **Anonymous submission**

#### Abstract

Pre-trained Large Language Models (LLMs) have been shown effective in various natural language processing tasks, especially after being fine-tuned on specific downstream scenarios. However, the full fine-tuning of LLMs is usually computationally expensive and time-consuming due to the ever-increasing large-scale parameters. In addition, while the LLMs are pre-trained to memorize the facts and knowledge from unstructured textual corpora, they cannot be well generalized to some domain-specific scenarios where additional structured knowledge is required, such as social interaction graphs or medical knowledge graphs. In this paper, we design a novel structure-aware adapter for LLMs to utilize structured relational information from knowledge graphs with a structure-aware relational attention mechanism. The proposed adapter framework only introduces a small scale of new parameters and therefore significantly reduces the cost of fine-tuning, without perturbing the initial pre-trained parameters of LLMs. We also propose a knowledge-graph-induced path-of-thought prompt to enhance the utilization of the LLM adapter to retrieve information from the knowledge graph. We evaluate the proposed model on two question-answering benchmarks. The evaluation results show that the proposed method outperforms the state-of-the-art LLM adapters by 4.1%-15.9% and 1.4%-17.6% in question-answering accuracy of CSQA and OBQA datasets. Ablation studies are also discussed to prove the effectiveness of the proposed modules.

## Introduction

Pre-trained Large Language Models (LLMs), such as LLaMA (Touvron et al. 2023), GPT-3 (Brown et al. 2020), Alexa Teacher Model (FitzGerald et al. 2022; Soltan et al. 2022), and RoBERTa (Liu et al. 2019), have achieved remarkable success in a wide range of natural language processing (NLP) tasks, such as question answering, language translation, text generation, text summarization, etc. The success of LLMs can be attributed to the massive number of model parameters, the pre-training on diverse and extensive text data, and the fine-tuning of specific tasks. However, the full fine-tuning of LLMs is usually computationally expensive and time-consuming. In addition, it can also lead to the problems of catastrophic forgetting and over-fitting, where the model forgets previously learned information or overfits as it adjusts to new task-specific data.

The adaption-based fine-tuning models freeze pre-trained

parameters of LLMs and only introduce a small scale of trainable parameters. The state-of-the-art adapters include the prompt-tuning adaption models such as LLaMA-Adapter (Zhang et al. 2023b; Gao et al. 2023), Prefix-Tuning (Li and Liang 2021), P-tuning (Liu et al. 2021b), and Prompt Tuning (Lester, Al-Rfou, and Constant 2021), as well as the low-rank parameter adaption models such as LoRA (Hu et al. 2021) and AdaLoRa (Zhang et al. 2023a). While the adaption models help significantly reduce the computational cost and adapt LLMs faster for various downstream tasks, they may still suffer from hallucination problems and generate factually incorrect content, when the pretrained knowledge is not well generalized to the new specific tasks. This can limit the application of adapted LLMs in some downstream scenarios where domain-specific or personalized knowledge is required, such as medical diagnosis (Varshney et al. 2023), social networks (Li et al. 2022), and personalized virtual assistant (Sun et al. 2022).

To address this challenge, additional external knowledge bases and knowledge retrieval mechanisms are required to enhance the adaption of LLMs. Knowledge graphs (KGs) have enormous potentials to encapsulate and condense rich structured and relational information that textual data inherently lacks (Schneider et al. 2022). In addition, with a domain-specific knowledge graph as additional input, the LLM can be trained to leverage domain-specific knowledge and relieve hallucination problems, especially for adaption methods that only update a limited scale of parameters. Many previous works have shown the effectiveness of integrating KGs into the *pre-training* (Zhang et al. 2019; Shen et al. 2020; Zhang et al. 2020; Wang et al. 2021) or *inference* (Baek, Aji, and Saffari 2023; Sun et al. 2021; Zhang et al. 2021) of LLM to enhancing various NLP tasks.

However, limited work has effectively integrated LLMs with KGs for *parameter-efficient adaption*. The CKGA (Lu et al. 2023) model has explored leveraging pre-trained knowledge graph embedding (KGE) to adapt BERT (Devlin et al. 2018), but it still requires an additional training objective of link prediction for graph convolutional networks (GCNs), and the LLMs cannot directly sense the structure of KGs. In this paper, we propose the **structure-aware adapter (SAA)** for LLMs to discerningly attend to the structure of knowledge graphs at a granular level. The framework of the SAA model is shown in Figure 1. We first ground and

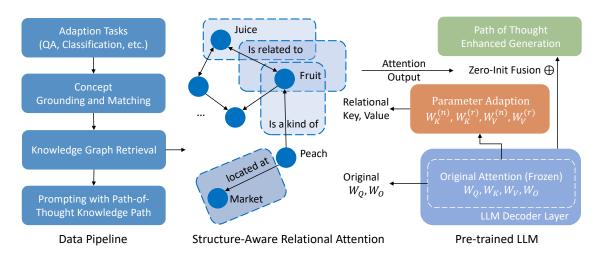

Figure 1: The framework of the proposed structure-aware adapter (SAA). The SAA model freezes the original attention weights and introduces parameter-efficient adapted weights of node and relation (in orange) for hierarchical structure-aware relational attention, the design of which is shown in Figure 2. A zero-init fusion is applied to integrate the outputs. The path-of-thought prompting for adaption training is also proposed to enhance the utilization of the retrieved knowledge graph.

match the concepts, and retrieve the knowledge subgraphs for input sequences. Then, we propose (i) the *structure-aware relation attention* for the pre-trained LLM to attend to an external knowledge graph. The proposed mechanism has a hierarchical attention strategy that attends to the source nodes in the first level and then attends to the relations and target nodes using relational attention in the second level. This technique allows the LLM to engage with the pivotal knowledge at a more intricate granularity while neglecting the redundant information. (ii) The *path-of-thought (PoT) prompting* method is also proposed to retrieve and integrate the reasoning path from the knowledge graph to enhance the adaption training of LLM. This enforce the LLM to learn to utilize the information from the knowledge graph.

We evaluate the proposed SAA adaption model in two public question-answering benchmark datasets, Common-SenseQA (CSQA) (Talmor et al. 2018) and OpenBookQA (OBQA) (Mihaylov et al. 2018). We compare the proposed model with state-of-the-art LLM adapter models, as well as their extensions which incorporate pre-trained knowledge graph embedding (KGE) or knowledge graph triplets. We train the adapter models over LLaMA-7B (Touvron et al. 2023) and LLaMA-3B (Geng and Liu 2023) and repeat the experiments for 5 times to report the average questionanswering accuracy and standard deviation. The evaluation result shows that the proposed SAA model outperforms the state-of-the-art LLM adapters by 4.1%-15.9% and 1.4%-17.6\% in question-answering accuracy of CSOA and OBOA datasets for LLaMA-7B. Ablation studies also show the effectiveness of the proposed structure-aware relational attention and path-of-thought prompting modules.

## **Structure-Aware Adapter**

In this section, we introduce the formulation of the tasks, as well as the formulation for the proposed structure-aware relational attention technique and path-of-thought prompt.

While the proposed method can be generalized to many large language models and tasks, in this section we focus on the most popular decoder-based language models and the question-answering task for the brevity of illustration.

## **Preliminaries and Formulation**

We model the adaption objective as the causal language modeling for the decoder-based language models such as LLaMA (Touvron et al. 2023). The causal language modeling involves autoregressively predicting the next token in a sequence given the previous tokens. Assume the tokens in the input sequence of length n is denoted as  $t_1, t_2, \cdots, t_n$ , the causal language modeling objective is formulated as,

$$p(t_i|t_1, t_2, \cdots, t_{i-1}) = \frac{\exp(\phi(t_i, t_1, t_2, \cdots, t_{i-1}))}{\sum_{t \in V} \exp(\phi(t, t_1, t_2, \cdots, t_{i-1}))},$$
(1)

where  $\phi(t,t_1,t_2,\cdots,t_{i-1})$  is a scoring function or model that computes the compatibility between the context and the candidate token t. Most natural language processing tasks can be modeled as an autoregressive text generation task with the causal language modeling objective and a prompt incorporating the original input and contexts. For example, we model the question-answering task with a prompt shown in Figure 3. The question-answering task provides the question context and choices as input, requiring the model the predict the correct choice. We use  $T_q = \{t_q^1, t_q^2, \cdots, t_q^n\}$  to denote the question tokens and  $T_c = \{t_c^1, t_c^2, \cdots, t_c^n\}$  for the choice tokens. The sequence after prompting is denoted as  $T = prompt(T_q, T_c) = \{t_1, t_2, \cdots, t_n\}$ .

In our task, the model receives an additional knowledge graph G as input. We assume the knowledge graph is a heterogeneous directed graph. This formulation can be generalized to most existing knowledge graphs or structured data. Assume there are N nodes and R relations. The adjacency matrix can be denoted as  $\mathbf{A} \in \mathbb{Z}_2^{N \times N \times R}$ .  $\mathbf{A}_{i,j}^k = 1$  represents there is an edge between the i-th node and j-th node

with k-th relation. In knowledge graphs, the feature of a node or a relation is represented by the representations denoted as x and r, respectively. Practically, the model retrieves subgraphs from the original full knowledge graph for each data sample, containing the related concepts, k-hop neighbors, and the respective relations. We denote the subgraphs with the same notation as illustrated above.

We focus on the adaption-based fine-tuning for LLMs, which freezes the original parameters (denoted as  $\Phi$ ) of LLMs pre-trained on the large-scale textual corpora. While the gradient computation via  $\Phi$  is still required, there is no update on the original parameters. In our model, the adaption-based fine-tuning model only introduces a small scale of new parameters (denoted as  $\phi^{\Delta}$ ,  $|\phi^{\Delta}| \ll |\Phi|$ ).  $\phi^{\Delta}$  can be represented as either parameter tuning for pretrained weight matrices like LoRA or prompt embedding like LLaMA-Adapter. The proposed structure-aware adapter tries to combine the advantage of both. The smaller amount of trainable parameters helps reduce the computation cost, speed up the training, as well as mitigate the catastrophic forgetting problem. However, it also raises new challenges of how to efficiently incorporate the knowledge from nontextual structured data and generalize to downstream scenarios, with limited trainable parameters. The proposed structure-aware adapter model focuses on two aspects to tackle this challenge: (i) We propose a new relational attention design that can efficiently leverage the relational information from the knowledge graph. (ii) We propose to enhance the knowledge reasoning using a path-of-thought prompt induced from the knowledge graph.

## **Structure-Aware Relational Attention**

The self-attention layers are the kernel modules of various pre-trained LLMs. Typically, the self-attention layer l will include weight matrices  $\mathbf{W}_Q$ ,  $\mathbf{W}_K$ ,  $\mathbf{W}_V$ , and optionally  $\mathbf{W}_O$ , for computing the queries, keys, values, and output mapping, respectively. We have  $\mathbf{W}_Q, \mathbf{W}_K, \mathbf{W}_V, \mathbf{W}_O \in \mathbb{R}^{d \times d}$  where d is the dimension of LLM hidden states. In the proposed Structure-Aware Relational Attention, we first adapt  $\mathbf{W}_K$ ,  $\mathbf{W}_V$  with the same adaption as LoRA (Hu et al. 2021) to produce the weight matrices for nodes (n) and relations (r) of the knowledge graph,

$$\begin{aligned} \mathbf{W}_{K}^{(n)} &= \mathbf{W}_{K} + \mathbf{P}_{K}^{(n)} (\mathbf{Q}_{K}^{(n)})^{\top} \\ \mathbf{W}_{K}^{(r)} &= \mathbf{W}_{K} + \mathbf{P}_{K}^{(r)} (\mathbf{Q}_{K}^{(r)})^{\top} \\ \mathbf{W}_{V}^{(n)} &= \mathbf{W}_{V} + \mathbf{P}_{V}^{(n)} (\mathbf{Q}_{V}^{(n)})^{\top} \\ \mathbf{W}_{V}^{(r)} &= \mathbf{W}_{V} + \mathbf{P}_{V}^{(r)} (\mathbf{Q}_{V}^{(r)})^{\top}, \end{aligned} \tag{2}$$

where the  $\mathbf{P} \in \mathbb{R}^{d \times z}$  and  $\mathbf{Q} \in \mathbb{R}^{z \times d}$  are low-rank decomposition matrices designed to adjust the original LLM weight matrices. z is the rank and we have  $z \ll d$ . Therefore, the matrix multiplication of  $\mathbf{P}\mathbf{Q}^{\top}$  contains much fewer parameters compared with  $\mathbf{W}$ .

The knowledge graph provides text descriptions for all the nodes and relations. In the proposed SAA model, we compute the node embeddings  ${\bf x}$  and relation embedding  ${\bf r}$  of the knowledge graph using the text descriptions. We apply

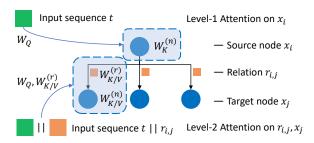

Figure 2: The proposed Structure-Aware Relational Attention. It computes the attention score based on a 2-level hierarchical structure. The model attends to the source nodes in level-1 and then attends to the relations and target nodes in level-2 using relational attention.

the same tokenization as LLM and use the output of the embedding layer to compute  $\mathbf{x}$  and  $\mathbf{r}$ . For those nodes and relations with k>1 tokens, we take the average embedding, i.e.  $\mathbf{x}=\frac{1}{|k|}\sum_i^k\mathbf{x}_i$ ,  $\mathbf{r}=\frac{1}{|k|}\sum_i^k\mathbf{r}_i$ . With the computed  $\mathbf{x}$ ,  $\mathbf{r}$ , and adjacency matrix  $\mathbf{A}$ , we design a 2-level hierarchical relational attention for the knowledge graph, the structure of which is shown in Figure 2.

The intuition of the proposed method is that we want to conduct external attention so that we can query the pertinent and effective knowledge from the knowledge graph. Therefore, for the computing of the query, we use the original weight  $\mathbf{W}_Q$ . For the keys and values, we apply the adapted matrices  $\mathbf{W}_K^{(n)}$ ,  $\mathbf{W}_K^{(r)}$ ,  $\mathbf{W}_V^{(n)}$ ,  $\mathbf{W}_V^{(r)}$  as introduced in Equation 2. In the first level of the hierarchical attention, we first compute the attention score  $\sigma^{(1)}$  between the input sequence  $\mathbf{T}$  and all the *source nodes*  $\mathbf{x}_i$ , which can be formulated as,

$$\sigma^{(1)}(\mathbf{T}, \mathbf{x}_i) = Softmax(\frac{(\mathbf{T}\mathbf{W}_Q)(\mathbf{x}_i \mathbf{W}_K^{(n)})^\top}{\sqrt{d}}), \quad (3)$$

where  $\mathbf{W}_Q$  is the pre-trained frozen weight from LLM.  $\mathbf{W}_K^{(n)}$  is the trainable weight of key for nodes. d is the dimension of hidden states. Note that while exploited, the formulation of *multi-head attention* is omitted here for brevity.

The relational attention, or graph transformer (Diao and Loynd 2022) was initially proposed to improve the reasoning of graph representation learning tasks. Inspired by relational attention, we propose the hierarchical relational attention for adapting LLMs to retrieve and incorporate the relational information from knowledge graphs. The idea of hierarchical relational attention is to concatenate the node representations with the relation representations, as well as concatenate the weight matrices. Then we compute the attention on a more fine-grained level. More specifically, for each edge triplet  $(\mathbf{x}_i, \mathbf{r}_{i,j}, \mathbf{x}_j)$  we have

$$\mathbf{q}_{i,j} = [\mathbf{T}; \mathbf{r}_{i,j}] [\mathbf{W}_{Q}^{\top}; \mathbf{W}_{Q}^{\top}]^{\top}$$

$$\mathbf{k}_{i,j} = [\mathbf{x}_{j}; \mathbf{r}_{i,j}] [(\mathbf{W}_{K}^{(n)})^{\top}; (\mathbf{W}_{K}^{(r)})^{\top}]^{\top}$$

$$\mathbf{v}_{i,j} = [\mathbf{x}_{j}; \mathbf{r}_{i,j}] [(\mathbf{W}_{V}^{(n)})^{\top}; (\mathbf{W}_{V}^{(r)})^{\top}]^{\top},$$
(4)

where T is the tokens of the input sequence.  $\mathbf{r}_{i,j}$  is the *relation* between node i and j.  $\mathbf{x}_{j}$  is the *target node*.  $\mathbf{W}_{Q}$  is

the original query weight matrix in the LLM attention layer. The computation can also be simplified as

$$\mathbf{q}_{i,j} = \mathbf{T}\mathbf{W}_{Q} + \mathbf{r}_{i,j}\mathbf{W}_{Q}$$

$$\mathbf{k}_{i,j} = \mathbf{x}_{j}\mathbf{W}_{K}^{(n)} + \mathbf{r}_{i,j}\mathbf{W}_{K}^{(r)}$$

$$\mathbf{v}_{i,j} = \mathbf{x}_{i}\mathbf{W}_{V}^{(n)} + \mathbf{r}_{i,j}\mathbf{W}_{V}^{(r)}.$$
(5)

With the above definition, the second-level attention weight  $\alpha^{(2)}$  and attention score  $\sigma^{(2)}$  can be computed as

$$\alpha_{i,j}^{(2)}(\mathbf{T}, \mathbf{r}_{i,j}, \mathbf{x}_j) = \frac{\mathbf{q}_{i,j}(\mathbf{T}, \mathbf{r}_{i,j}) \mathbf{k}_{i,j}^{\top}(\mathbf{r}_{i,j}, \mathbf{x}_j)}{\sqrt{d}}$$

$$\sigma_{i,j}^{(2)} = \frac{\exp(\alpha_{i,j}^{(2)})}{\sum_{\mu \in \mathcal{N}_i} \exp(\alpha_{i,\mu}^{(2)})},$$
(6)

where  $\mathcal{N}_i = \{\mathbf{x}_j | \mathbf{A}_{i,j}^k \neq 0\}$  represents all the neighbors of node i w.r.t. any relation  $\mathbf{r}^k$ . We compute the final attention score by

$$\sigma_{i,j}^{(KG)} = \sum_{i,j} \sigma_i^{(1)} \mathbf{A}_{i,j} \sigma_{i,j}^{(2)}$$
 (7)

Finally, we fuse the output of structure-aware relational attention with the original output of LLM with a zero-init gate (Zhang et al. 2023b),

$$\mathbf{h_t^l} = \mathbf{W}_O([\sigma^{(KG)} \cdot g; \ \sigma^{(LLM)}] \cdot [\mathbf{V}^{(KG)}; \mathbf{V}^{(LLM)}]), \ (8)$$

where g is the zero-init gate and the semicolon represents concatenation.  $\mathbf{W}_O$  is the output mapping in the original LLM attention.  $\sigma^{(LLM)}$  is the original softmax attention score for the input sequence T.  $\mathbf{V}$  is the value matrix in Equation 5, we have  $\mathbf{v}_{i,j} \in \mathbf{V}$ .  $\mathbf{h}^1_{\mathbf{t}}$  is the output hidden state for the token t at layer t.

The proposed structure-aware relational attention can be applied to adapt multiple attention layers of original LLM attention. Practically, we adapt the last L layers of attention layers. With multiple adapted layers fused with the proposed KG attention, the LLM can learn to attend to a complex graph structure. Compared with the existing method which directly attends to textual triplets of trained KG representations, the proposed hierarchical relational attention mechanism adapts LLM to attend to the graph structures in a more fine-grained manner. In addition, since the knowledge graph usually contains a lot of redundant information (Akrami et al. 2020), the proposed relational attention also enables the LLM to selectively retrieve the essential information and neglect the redundant or unrelated nodes and relations.

# Enhance Knowledge Reasoning with Path-of-Thought Prompt

In the previous section, we have introduced structure-aware relational attention, which retrieves and fuses the fine-grained knowledge output from the knowledge graph (KG). While it provides the LLM with an additional knowledge base to retrieve information and generate informative sentence expressions, an additional technique is required to enforce the utilization of LLM on KGs. One possible solution of existing work is to pre-train the LLM with the KG module

Given the following question, pick the best answer from the given choices.

Question: The only baggage the woman checked was a drawstring bag, where was she heading with it?

Choices:

- (A) garbage can
- (B) military
- (C) jewelry store
- (D) safe
- (E) airport

Answer: (E) airport

Contexts: drawstring is part of drawstring bag, drawstring bag is at location of airport. baggage is at location of airport

Figure 3: Example of an induced path-of-thought prompt in CSQA training dataset. During the inference in the test or validation set, the italic sentences are the expected generation. The sentence after "Contexts:" is the path-of-thought path retrieved from the knowledge graph.

on additional large textual corpora (Yasunaga et al. 2022). However, the computation cost of additional pre-training is contradicting our objective of fast and efficient LLM adaption. Therefore, we propose a knowledge-induced path-of-thought prompt to enhance the utilization of KGs.

The idea of the proposed path-of-thought prompt is inspired by the chain-of-thought prompt (Wei et al. 2022), which was proposed to enhance the zero-shot inference of LLM, where several examples with manually labeled chainof-thought contexts are provided before we input the actual sequence into the LLM. In our case, instead of prompting at inference time, we retrieve and integrate path-of-thought in the training prompt to enhance the adaption training. More specifically, we design an algorithm to retrieve the reasoning path between pairs of matched concepts in KG. We denote the concepts from the question as  $c_q \in C_q$ , the choice concepts as  $c_p \in C_p$ , and the concepts of correct choice (answer) as  $\hat{c}_p \in \hat{C}_p$ . Then, for every pair of concepts from  $(c_q, c_p) \in C_q \times \hat{C}_p$ , we compute the shortest paths between them using Dijkstra algorithm (Cormen 2001). Finally, we concatenate the text of nodes and relations along the shortest paths to form the final prompt, together with the question, choices, and answer. One example of computed pathof-thought prompts is shown in Figure 3.

This technique is different from the previous works transforming the KG triplets or knowledge contexts into texts as additional input (Wang et al. 2021; Baek, Aji, and Saffari 2023). In the proposed path-of-thought prompting, the retrieved reasoning path works as the additional learning objective instead of input. The proposed prompting actually enforces the adapted LLM to (i) generate the answer prediction as well as (ii) generate the context of the reasoning path. This additional objective, therefore, enhances the model to utilize the information from KG.

# **Experiments**

In this section, we introduce the evaluation experiments and an ablation study to verify the functionality of the proposed structure-aware relational attention module and pathof-thought prompting. We focus on the question-answering task which emphasizes the knowledge reasoning of LLMs.

## **Dataset and Pre-trained LLMs**

We evaluate the proposed models and baselines on two public question-answering benchmark datasets.

- CommonSenseQA (CSQA): The CSQA dataset (Talmor et al. 2018) is a 5-choice question answering benchmark which requires different types of commonsense knowledge to predict the correct answers. This dataset includes 9741 samples in the train set, 1221 in the validation set, and 1140 in the test set. Since the label of the test set in CSQA is not publicly available, we report the evaluation result in the validation set.
- OpenbookQA (OBQA): OBQA (Mihaylov et al. 2018) is another advanced 4-choice question-answering dataset, probing a deeper understanding of the topic and the language it is expressed in. While the OBQA dataset also provides salient facts summarized as an open book, it is not used in our experiments for a fair comparison. The OBQA dataset includes 4957 samples for training, 500 for validation, and 500 for testing. In OBQA the label of the test set is publicly available.

In the experiments, we use two pre-trained LLMs as the base models for adaption: (i) **LLaMA-7B**<sup>1</sup>, a pre-trained LLaMA model (Touvron et al. 2023) by Meta AI containing 7 billions of parameters. (ii) **LLaMA-3B**<sup>2</sup>, a smaller pre-trained LLaMA model contributed by OpenLM Research (Geng and Liu 2023), containing 3 billions of parameters.

### **Baselines**

We compare our model with the following baselines.

- **Zero-Shot**: We directly apply the pre-trained LLM for a generation without any fine-tuning or adaption.
- LLaMA-Adapter (Zhang et al. 2023b): The state-ofthe-art prompt-embedding-based adapter for LLM. We apply LLaMA-Adapter to the last 20 attention layers with adaption prompt length equal to 10. The implementation is based on peft library<sup>3</sup> (Mangrulkar et al. 2022a). All the other setting remains the same as the paper.
- LLaMA-Adapter + KGE: Extension of the LLaMA-Adapter model to incorporate the pre-trained knowledge graph embedding (KGE), using the same framework of the image-incorporated extension of LLaMA-Adapter (Zhang et al. 2023b) with linear projection.
- LLaMA-Adapter + KG triplets: The extension of the LLaMA-Adapter model where we extract and integrate up to 100 tokens of triplets from KGs to the input prompt.
- LoRA (Liu et al. 2019): The state-of-the-art parameter adaption model for LLMs is based on trainable rank decomposition matrices. We apply LoRA to the last 20 attention layers. The learning rate is set as 0.0003. The low-rank dimension and alpha are set as z=2 and  $\alpha=8$ . The implementation is based on peft library.

- LoRA + KGE: The extension of the LoRA model to integrate the linear-mapped pre-trained KGE from Concept-Net. External attention is applied to KGE.
- LoRA + KG triplets: Extension of the LoRA model to include up to 100 tokens of triplets transformed from KGs. We integrate the triplets with the prompt.
- LLaMA-Adapter + LoRA: We simultaneously apply the LLaMA-Adapter for prompt adaption and LoRA for parameter adaption, both applied to the last 20 attention layers with z=2,  $\alpha=8$ , and 10 adaption prompts.

## **Implementation and Environments**

All the experiments are conducted on AWS G5 instances with 8 Nvidia A10G GPUs, 192-core CPUs, and 748GB memory. The implementation is based on Python 3.10.11 and PyTorch 2.0.0. The implementation utilizes the accelerate<sup>4</sup> and deepspeed<sup>5</sup> libraries for distributed training.

#### **Evaluation Metrics**

We provide the model a prompt containing the questions, choices, and optionally path-of-thought contexts as is shown in Figure 3. During inference, we have the adapted LLM to generate the next 5 tokens after the "Answer:" in the prompt. We use the multiple choice symbol binding (MCSB) method (Robinson, Rytting, and Wingate 2022) to compute the prediction label. More specifically, we find the choice token (e.g. "(A)") with the maximum number of appearances and use it as the model prediction. Finally, we report the accuracy of question answering as the evaluation metric. We repeat all the experiments for 5 times and report the average accuracy and the standard deviation.

## **Experimental results**

We retrieve a knowledge sub-graph for each of the question-answering samples during pre-processing with reference to the retrieval algorithm introduced in DRAGON (Yasunaga et al. 2022). We first retrieve and match the concepts of the knowledge graph for questions and choices after Lemmatization. The average numbers of matched concepts in CSQA and OBQA datasets are 14.04 and 14.59. Based on the matched concepts, we further retrieved the 2-hop neighbors of concepts  $C_i$  with a pre-trained RoBERTa (Liu et al. 2019) to maximize  $\sum_{t \in C_i} \log p(t|Q)$  where Q is the question and t is the token in a concept. We select the top neighbor concepts to construct a subgraph with 100 concept nodes.

We compare our proposed structure-aware adapter model with the baselines in both the CSQA and OBQA datasets. The learning rate is set as 0.0003. We apply the proposed adapter to the last 20 layers of LLM attention, the same as the settings of baselines. The low-rank dimension and alpha are set as z=2 and  $\alpha=8$  for the adaption of weight matrices. In our model with the path-of-thought prompting, we limit the maximum length of the shortest path of thought as 50 tokens in the training prompt. The experimental results of the proposed structure-aware adapter and the baselines are

LoRA + KG triplets	$0.6644^{\pm0.0050}$	$0.6696^{\pm0.0112}$	$0.3735^{\pm0.0925}$	$0.6048^{\pm0.0119}$
LLAMA-Adapter + LoRA	$0.6994^{\pm0.0032}$	$0.6396^{\pm0.0067}$	$0.6624^{\pm0.0102}$	$0.6100^{\pm0.0163}$
Structure-Aware Adapter (Ours)	$0.7100^{\pm 0.0058}$	$0.6715^{\pm 0.0042}$	$0.6650^{\pm 0.0115}$	$0.6140^{\pm 0.0171}$

shown in Table 1. The proposed structure-aware adapter outperforms the state-of-the-art baselines. When adapting on LLaMA-7B in the CSQA dataset, our model achieves 15.9% and 4.1% higher accuracy than LLaMA-Adapter and LoRA, respectively. When adapting on LLaMA-7B in the OBQA dataset, our model achieves 17.6% and 1.4% higher accuracy than LLaMA-Adapter and LoRA.

We also compare the proposed model with several extensions of LLaMA-Adapter and LoRA enhanced with pretrained knowledge graph embedding (KGE) or textual KG triplets. In the KGE extensions, we integrate the pre-trained KGE of the matched concepts and related neighboring concepts by applying a linear mapping, and then adding to the prompt embedding of LLaMA-Adapter or applying LoRAadapted external attention on KGE. The pre-trained KGE improves the performance of LoRA in most cases of datasets and PLMs. This is because the KGE is pre-trained to include the information of relations and adjacency concepts, which serve as external knowledge for LoRA to answer questions. The KG triplets also help the adaption models in the question-answering task, especially for LLaMA-Adapter on the OBQA dataset. However, integrating either the pretrained KGE or the textual KG triplets is not optimal. While already being filtered with some rule-based pre-processing, there is still a lot of redundant information stored in KGE as well as KG triplets. The methods incorporating KGE and KG triplets do not allow the LLM to sense the relational structure and selectively retrieved the key information. The proposed structure-aware relational attention naturally allows LLM to attend to the relational structure of KG at a more fine-grained level, which enhances the ability of the proposed module to de-noise the redundant information and achieve higher average accuracy in the experiment.

In addition, we study the effectiveness of the proposed model and baselines on a LLaMA-3B model, which contains fewer parameters and is pre-trained on smaller and unofficial corpora, and fewer sub-tasks. The adaption in LLaMA-3B is more challenging because it contains much less pre-trained knowledge and, meanwhile, it's more difficult to enforce it to leverage the external knowledge from KG. In this case, we observe the adaption training of many baselines be-

comes unstable and sometimes fails to converge. This leads to lower average accuracy scores and high standard deviation. The instability of training is especially significant after incorporating the KGE and KG triplets. While the proposed structure-aware adapter also leverages external knowledge, we in addition propose the path-of-thought prompting to enforce the model to attend to the structure of the knowledge graph and therefore stabilize the training. Compared with the baselines, the training of the proposed model is more stable and we do not observe a collapse of convergence.

Table 2: Ablation study of the Structure-Aware Adapter, after removing Relational Attention, replacing with Node Attention, or removing the path-of-thought (PoT) prompting

Model Name	CSQA	OBQA
Without Rel. Attention	$0.6968^{\pm0.0074}$	$0.6608^{\pm0.0231}$
With Node Attention	$0.6915^{\pm0.0089}$	$0.6542^{\pm0.0068}$
Without PoT	$0.7076^{\pm0.0096}$	$0.6674^{\pm0.0093}$
Structure-Aware Adp.	$0.7100^{\pm 0.0058}$	$0.6715^{\pm 0.0042}$

## **Ablation Study**

We conducted ablation studies to evaluate the effectiveness of the proposed modules of the structure-aware adapter. We removed or modified the proposed modules to form the following ablation experiments.

- Without Relational Attention: We remove the proposed structure-aware relational attention and use a typical attention mechanism to attend to the average embeddings of relations  $r_{i,j}$  and target nodes  $x_j$ .
- With Node Attention: We simplify the proposed method to attend to only the nodes  $x_j$  of matched or related concepts in the retrieved knowledge subgraph.
- Without Path-of-Thought: The proposed SAA model without the path-of-thought (PoT) prompting, where we train the model without the "Contexts:" part.

The experimental result is shown in Table 2. By removing the proposed hierarchical relational attention for the knowledge graph, the accuracy decreases for 1.32% and 1.07%

respectively in CSQA and OBQA datasets, which illustrates the effectiveness of the relational attention. A further simplified ablation model is the one with node attention, which ignores the relation features and only attends to the matched concepts or their neighbors. We also observe a decrease of 1.85% and 1.73% in both datasets. While the neighbors of matched concepts also provide contexts for solving the question-answering task, neglecting the relations and graph structure leads to a significant decrease in the accuracy metrics. Finally, we also study the model without the proposed path-of-thought prompting. After removing PoT, there is a observed accuracy reduction in both datasets and the standard deviation also increases. This shows the benefit of applying the path-of-thought prompting in enhancing knowledge utilization and training stabilization.

### **Related Works**

Large Language Model Adaption The adaption-based model fine-tuning, or parameter-efficient fine-tuning (PEFT) for large language models (Mangrulkar et al. 2022b) freezes the parameters of the initial pre-trained large language models and only introduces a small number of trainable parameters to save computational costs and preserve the pre-trained linguistic knowledge. The existing work has explored the prompt-tuning adaption methods (Zhang et al. 2023b; Li and Liang 2021; Lester, Al-Rfou, and Constant 2021; Liu et al. 2021b,a; Qin and Eisner 2021) and parameter weight adaption methods (Hu et al. 2021; Zhang et al. 2023a; Hedegaard et al. 2022). One representative work of prompt-tuning is the LLaMA-Adapter (Zhang et al. 2023b), which attaches the embedding of the trainable adaption prompts as a prefix along with the input sequence and introduces a zero-init fusion mechanism to integrate the output of adaption prompt to the language model. The LoRA model (Hu et al. 2021) is a parameter weight adaption model proven to be effective in adapting the model for various generative tasks, the performance of which is close to the full fine-tuning of original large language models (LLMs). While the existing adaption models show promising performance in adapting PLMs to various downstream tasks, these methods may still suffer from hallucination problems and generate factually incorrect content due to limited trainable parameters for domain transferring. The adaption models still rely on the knowledge from the textual pre-training corpora and cannot utilize some external knowledge, which limits their application of domain-specific scenarios. In this paper, we propose a structure-aware adapter for PLMs that utilize the structured data to enhance the downstream generative tasks.

Knowledge Graph Enhanced Language Modeling The knowledge graph, such as ConceptNet (Speer, Chin, and Havasi 2017), Wikidata (Vrandečić and Krötzsch 2014), is a structured knowledge base that has been proven to be effective in improving the performance of LLM on various natural language processing tasks (Pan et al. 2023). Many other graphs such as social graphs and entity interaction logs can also be represented as the knowledge graph to enhance LLMs (Li et al. 2022; Chang et al. 2021; El-Kishky et al. 2022). The exiting researches have explored utilizing the

knowledge graph for improving the LLM **pre-training** such as ERNIE (Zhang et al. 2019), GLM (Shen et al. 2020), E-BERT (Zhang et al. 2020) KEPLER (Wang et al. 2021), K-BERT (Liu et al. 2020), **inferences** such as QA-GNN (Sun et al. 2021), GreaseLM (Zhang et al. 2021), KGLM (Logan IV et al. 2019), DRAGON (Yasunaga et al. 2022), and KAPING (Baek, Aji, and Saffari 2023).

However, limited research has focused on enhancing the adaption of LLM with knowledge graph, while the adaption methods have become more and more interesting due to the ever-increasing scale of PLM parameters. The CKGA (Lu et al. 2023) model has explored leveraging pre-trained knowledge graph embedding to adapt BERT (Devlin et al. 2018), but it still requires an additional training objective of link prediction for graph convolutional networks (GCNs) and the LLM cannot directly attend to the structure of KGs. The existing research has explored the mechanisms to integrate the information from the knowledge graph. Some of the existing methods transforms the knowledge graph triplets like ERNIE (Zhang et al. 2019), SKILL (Moiseev et al. 2022), and KAPING (Baek, Aji, and Saffari 2023), or retrieved knowledge contexts such as KEPLER (Wang et al. 2021) into text as additional input. However, the additional textual input usually cannot well represent the complex graph structure and may introduce additional noise. Some related works focus on generating KG entity embeddings as additional input for the language models such as KI-BERT (Faldu et al. 2021) and NTULM (Li et al. 2022). The other works exploit joint training of link prediction and masked language modeling (MLM) objectives for the pretraining of LLM, such as DRAGON (Yasunaga et al. 2022) and KEPLER (Wang et al. 2021). However, these methods usually use a single fusion bottleneck between LLM and the graph module and usually train additional graph neural networks (GNN) to encode the node embeddings, Therefore, the LLMs cannot directly attend to the structure of KG. On the contrary, we propose the structure-aware relational attention that allows the LLM to naturally attend to structures of the knowledge graph without bottleneck networks or additional graph learning objectives during the adaption training.

## Conclusion

This paper proposes an innovative structure-aware adapter for parameter-efficient fine-tuning of large language models, leveraging structured and relational information from knowledge graphs. We propose structure-aware relational attention to attend to knowledge graphs at a granular level, enabling it to discerningly incorporate essential information while concurrently disregarding superfluous or redundant details. In addition, a novel algorithm is proposed to extract the reasoning paths from knowledge graphs and compute the path-of-thought prompts to enhance the LLM adapter's efficacy in knowledge extraction. The evaluation result in two question-answering benchmark datasets demonstrates that the proposed approach surpasses the leading LLM adapters and their variants in question-answering accuracy. A comprehensive analysis of ablation studies further substantiates the effectiveness of the newly introduced components in enhancing the model's performance.
